TUMOUR METASTASIS GENE

5

Background

Metastatic spread of tumours from the site of primary growth to distant organs, where seedling tumours are formed by disseminated cells, is the most 10 clinically important property of malignant tumours. It endows the community of tumour cells with the ability to survive surgical excision of the primary growth. Also, because metastases can themselves act as foci for further shedding and dissemination of tumour cells, 15 this process forms the basis for a geometric increase in the impact of the tumour on the host and increasing difficulty in clinical management, because of the wide dispersal of the tumour burden. The magnitude of the effect of this phenomenon on human health can be 20 appreciated by reference to the mortality statistics published by the Registrar General of the United Kingdom. Approximately one in three of the population die of the consequences of metastatic cancer, or are found to harbour asymptomatic metastatic tumour deposits 25 at autopsy. Research to obtain data which could be helpful in early assessment of tumour prognosis or in preventing the growth of already established metastases is therefore directed at controlling a major and clinically significant problem. The following work was 30 undertaken as a contribution to such an endeavour.

Current Work

In work recently conducted in the inventors laboratory it has been found that, if one is 35 sufficiently persistent, it is feasible to transfer metastatic capability from human metastatic tumour

cells to non-metastatic mouse tumour cells, by transfection with genomic DNA from the metastatic population (Tarin 1988). On inoculation into nude mice the transfected cells make many metastatic deposits in 5 various organs. The new phenotype is stable through many cell generations and can be transferred again in a second round of transfection, using DNA from metastases formed by the primary transfectants which we have introduced into fresh cells of the non-metastatic mouse 10 cell-line. Subsequently it has been demonstrated in this programme of work that concomitant transfer of the donor DNA (of human origin) through both rounds of transfection, can be detected by several convergent lines of evidence, including Southern blotting, Alu-PCR 15 and in situ hybridisation (Hayle, Darling, Taylor and Tarin, 1993) using human Alu-specific probes with appropriate controls. Still more recently this work has led to the isolation of clones containing human 20 DNA, from the transfected metastatic cells by making a genomic library of their DNA, in cosmids and screening it with human Alu specific probes. From one of the bacterial clones so identified it was possible to subclone a 2.9 Kb DNA Fragment that hybridises 25 specifically to Southern blots of human DNA to identify a sharp homologous band suggestive of a sequence present in single or low copy number. This indicates that the homology is not to multiple iterative sequences, present in the human genome, which would have been expected to produce a smear. (It should be 30 mentioned that, to visualise the band, non-specific cross hybridisation of Alu repeats in the probe to counterparts in the target human DNA, was blocked with excess unlabelled Alu DNA prepared by PCR).

The fragment has been sequenced and 35 comparison of this information with entries in the GenBank/EMBL DataBank, indicates that it contains human

DNA which has not been previously recorded. Further analysis of the sequence by computer programmes to detect coding regions as well as by Northern blotting and by reverse transcription-polymerase chain reaction (RT-PCR) techniques, has provided converging lines of evidence that parts of it are vigorously transcribed (expressed) in malignant human tumours and their metastases, but not comparably so in non-neoplastic tissue. The significance of this finding is that the sequence has the potential to be a valuable probe for the accurate assessment of the prognosis of patients with malignant tumours, by examination of a tiny biopsy sample or even a few cells obtained by fine needle aspiration, and thus to influence therapy.

15

The Invention

The invention provides the 2858bp DNA whose sequence (SEQ ID NO: 1) is shown in the Figure.

The invention also provides a nucleic acid which codes for a protein which is expressed in malignant human tumours and their metastases, which nucleic acid is selected from: the 2858bp DNA whose sequence (SEQ ID NO: 1) is shown in the figure, degenerated and allele variations thereof, fragments thereof, longer DNA chains comprising any of these, and DNA which hybridises to any of these.

The nucleic acid can be incorporated into an expression vector, and the vector into a microorganism. The expression vector and the transformed microorganism constitute further aspects of the invention.

In another aspect, the invention provides use of the defined nucleic acids or derivatives or fragments thereof for the identification, preparation or isolation of the nucleotide sequence or portions thereof coding for a protein which is expressed in malignant human tumours and their metastasis. Thus the

inventor intends to proceed with blotting, PCR and library screening techniques, to search for related flanking sequences and cDNA clones. In this way, it is hoped to recover stretches of human DNA which are worth 5 testing in functional assays to evaluate their metastatic inductive capability. These experiments may include reintroduction of the defined expression vectors into non-metastatic tumour cell lines.

The invention also provides a method of 10 investigating metastasis which method comprises obtaining a sample of cells, and analysing the sample for the nucleic acid of the 2858bp nucleic acid fragment or for a complementary RNA sequence. This analysis may preferably involve the use of reverse 15 transcriptase to form cDNA corresponding to RNA of the sample; amplifying the cDNA, e.g. by the polymerase chain reaction; and performing a hybridisation assay of the amplified DNA using as a hybridisation probe a fragment or the whole of the defined DNA.

20 The sample of cells may be a clinical sample of body fluid (e.g. blood, urine, sputum or stool) or body tissue (e.g. tumour tissue) of a patient. The sample may be a histological section which is probed using a fluorescent or other labelled probe for mRNA 25 corresponding to the 2858bp nucleic acid fragment.

Experimental

Computer analysis has indicated that the 30 sequence contains sections with characteristics signifying high probability that they are coding regions. Several studies were performed on this 2.9 Kb fragment to examine its informational content using various suites of programmes available via the Oxford 35 University VAX cluster. These included looking for coding sequences by locating the positions of potential

- 5 -

start codons and by seeking stretches which have no stop codons. Further methods used included codon preference analysis (i.e. examination of whether the order of arrangement of purine and pyrimidine bases is characteristic of coding sequences), as well as searches for probable splice junction sites and other more specialised techniques, to confirm that some of the open reading frames so detected are coding regions. This information was used to design PCR primers to the boundaries of one of the coding regions which particularly attracted interest and with the RT-PCR technique showed that one could specifically amplify homologous mRNA sequences from RNA extracted from metastatic human tumour cell lines. The exact sequences of the primers used was as follows:

P1 5' AATGACCCAGGAATGTCCAGGCC (SEQ ID NO: 2)
P2 5' GAGGAGCACCTCACAGGCATCAA (SEQ ID NO: 3)
P3 5' ACGTGTGCGAGAGCAGTGTGCTGT (SEQ ID NO: 4)
P4 5' TCTCACACCCATCTGGCTCCCACA (SEQ ID NO: 5)

and the positions of these are marked on the sequence above.

Computer analysis of the sequence of the new DNA fragment

The sequence was analysed using the Genetics Computer Group (GCG) package on the Oxford University molecular biology VAX cluster, the BLAST network service at NCBI and the mail servers Grail, Netgene and GeneID. The Grail mail server is trained to recognise potential coding regions in human DNA; NetGene also uses a neural network to approach to predict splice sites in vertebrate genes; and the GeneID mail server uses a hierarchical rule based system to recognise potential vertebrate coding genes.

Database searches were made at Oxford against EMBL release 34.0 and SwissProt release 25 and at NCBI.

- 6 -

against the non redundant DNA database (containing EMBL release 34.0 and GenBank release 76.0) and the non redundant protein database (containing SwissProt release 25, PIR release 36 and GenPept release 76).

5 The DNA sequence was searched against the EMBL and Genbank databases using the GCG implementation of the FASTA program and the NCBI BLAST service to look for homologies to any known sequences. No homology to any known coding regions were found. At the 3' end a
10 strong homology to a rodent Alu-like repetitive sequence was found, suggesting that the 3' end contains a rodent sequence. The remainder of the DNA fragment contained scattered sequences with similarity to higher primate Alu repeats and several short segments with
15 familial resemblances to sections of a variety of human genes, but no significant resemblances to rodent genes. This supports the Southern blotting data that the cloned sequence is mainly a portion of human genomic DNA retrieved from the mouse genome of the cells into
20 which it was transfected. The sequence, translated in all six frames, was searched against the protein databases. No homologies to any known protein sequences were seen.

25 The GCG program CodonPreference was used to display potential open reading frames (i.e. stretches of sequence without a frame stop codon); and to predict the likely coding regions, based on the degree of codon bias shown towards a reference codon usage set of highly expressed human genes. The level of GC bias
30 and codon usage bias were seen that corresponded to possible open reading frames (ORFs). Among the most notable is the region from approximately bases 1650 to 1800 in the 2nd reading frame of the reverse strand.

35 The entire sequence was submitted to the NetGene, GeneID and Grail mail servers to detect potential splice sites, genes and exons. Grail

predicted three possible exons, one in the forward strand in frame 2 (between bases 536 and 942) and two in the reverse strand, in frames 1 (between bases 2143 and 2398) and 2 (between bases 1625 and 1907). These 5 three regions all corresponded to exons predicted by GeneID and also to donor and acceptor sites found by NetGene (see Table 2). All three exons fell within regions of higher than expected codon preference and GC bias as predicted by CodonPreference analysis. The 10 region around the possible exon in the second frame of the reverse strand was therefore the first one chosen for further study, being the one with the highest probability of being a coding region.

The whole DNA sequence was also examined for 15 potential transcription factor coding domains and binding sites by searching against the release 6.3 of the Ghosh database using GCG FindPatterns. Although some tentative matches were found a detailed study of the compositions of these and their locations in the 20 three reading frames indicated that these were all very unlikely to be true transcription factor coding regions. The translated sequence was also searched against release 10.1 of the Prosite database to search for potential DNA binding regions using the GCG program 25 Motifs, but no homology to previously recorded regions could be identified.

Investigation of expression

Evidence that one of the putative coding 30 regions identified by computer analysis in this fragment is expressed in neoplastic or metastatic tumour tissue, was provided by experiments using the techniques of Northern blotting and RT-PCR. Northern blots of mRNA from metastatic cell lines A375M (the 35 donor of the DNA used for the original transfection of metastatic behaviour) and 4A4 (a clonal line derived

(Bao *et al*, 1992) from the human breast carcinoma cell line MDA-MB-435) probed with a ^{32}P labelled sample of the full 2858 base pair sequence showed specific hybridisation to two small transcripts of approximately 5 300bp size, but no comparable homology to mRNA from a virtually non-metastatic cell line 2C5 cloned from MDA-MB-435.

Reverse Transcription - Polymerase Chain Reaction (RT-PCR)

10 Messenger RNA extracted from cell lines and solid tissue samples was reverse transcribed with viral reverse transcriptase and the cDNA so obtained specifically amplified with primers P1 and P4 designed to anneal to the outer ends of the putative coding 15 region identified by computer analysis between base 951 and 1233 on the reverse strand of the 2858 base pair complete sequence. Samples were also amplified using primers P2 and P4. The PCR products were separated by gel electrophoresis in 1.6% agarose and stained with 20 ethidium bromide for viewing in a U-V transilluminator. After photography the gels were blotted on to Hybond N⁺ (Amersham International plc) nylon membranes and probed with ^{32}P gammaATP end-labelled oligonucleotide P3. After hybridisation the filters were washed and exposed 25 to Kodak x-ray film for 2-10 hours, after which the film was developed.

The PCR cycle parameters were as follows: 1 period at 94°C for 4 minutes, followed by 1 period at 82°C for 2 minutes, during which time the Taq enzyme 30 was added, followed by 30 cycles of 92°C for 30 seconds, 60°C for 30 seconds and 70°C for 2 minutes.

Control studies to monitor the quality of mRNA and the success of cDNA synthesis in the RT-PCR techniques were conducted using 2 μl aliquots from the 35 same samples amplified with primers to the human β -actin gene (Clontech Laboratorie Inc., Palo Alto, CA).

- 9 -

When blots of PCR products of cDNA obtained by reverse transcription of mRNA from these cell lines and amplified by primer pairs P1 and P4 and P2 and P4 were probed with oligonucleotide P3 strong

5 hybridisation was seen to bands of the predicted sizes in the tracks containing samples from the metastatic cells (A375M and 4A4) and weak hybridisation to similar sized bands in the track containing sample from the virtually non-metastatic cell line (2C5).

10 Evidence of expression of the coding region in tissues from human primary tumours and their metastases has also been obtained using RT-PCR with the primers chosen. In a preliminary survey of fresh samples from such lesions and from normal tissue

15 counterparts (Table 1) disproportionately large quantity of specific PCR product corresponding to the amplified segment was observed in samples from metastases and matched primary tumours from all 4 malignant cases studied. In 9 samples from

20 corresponding normal tissues only trace expression was detectable. This trace was not visible on ethidium bromide stained gels and required blotting and probing with ³²P labelled oligonucleotide P3 to be detected (Table 1).

25 Samples from 2 benign tumours showed very low expression (Table 1). Collectively these results confirm that the coding region identified in the 2858 bp cloned DNA fragment is expressed in the malignant tumours examined and indicate that homologous transcripts are present only in trace amounts in the non-neoplastic tissue samples. Expression was also low in the benign (i.e. non-invasive non-metastatic) tumours studied.

CLAIMS

1. The 2858bp DNA whose sequence is shown in
5 the figure (SEQ ID NO: 1).
2. A nucleic acid which codes for a protein
which is expressed in malignant human tumours and their
metastases, which nucleic acid is selected from: the
2858bp DNA whose sequence is shown in the figure,
10 degenerated and allele variations thereof, fragments
thereof, longer DNA chains comprising any of these, and
DNA which hybridises to any of these.
3. An expression vector comprising the nucleic
acid of claim 1 or claim 2.
- 15 4. A transformed microorganism comprising the
expression vector of claim 3.
5. Use of the nucleic acid of claim 1 or claim 2
or derivatives or fragments thereof for the
identification, preparation or isolation of a
20 nucleotide sequence or portion thereof coding for a
protein which is expressed in malignant human tumours
and their metastases.
6. A method of investigating metastasis which
method comprises obtaining a sample of cells, and
25 analysing the sample for the nucleic acid of claim 1 or
claim 2 or for a complementary RNA sequence.
7. A method as claimed in claim 6, wherein the
sample of cells is a clinical sample obtained from body
fluid or body tissue of a patient.
- 30 8. A method as claimed in claim 6 or claim 7,
which method comprises making cDNA from mRNA in the
sample, amplifying a portion of the cDNA comprising at
least part of the DNA of claim 1, and detecting the
amplified DNA.
- 35 9. A method as claimed in claim 8, wherein the
cDNA is amplified by means of the polymerase chain

- 18 -

reaction using as primers

P1 5' AATGACCCAGGAATGTCCAGGCC (SEQ ID NO: 2) or

P2 5' GAGGAGCACCTCACAGGCATCAA (SEQ ID NO: 3) and

P4 5' TCTCACACCCATCTGGCTCCCACA (SEQ ID NO: 5).

5 10. A probe which is a labelled oligonucleotide

P3 5' ACGTGTGCGAGAGCAGTGTGCTGT (SEQ ID NO: 4).
